Nivel de coliformes en agua potable

Parámetros	Unidades	Limite máximo permisible
Giardia lamblia	Quistes/L	0/20 L
Coliformes fecales o E. coli	NMP/100 ml o UFC/100 ml	Ausente
Microcistina-LR*	µg/L	1,0

* Determinar sólo en el caso que la turbiedad esté por arriba de 0.5 UTN.

Parámetros	Unidades	Limite máximo permisible
Tricloroetileno	µg/L	50
Bromoclorometano	µg/L	100
Bromoforno	µg/L	200
Cloroforno	µg/L	100
Dibromoclorometano	µg/L	200
Ácidos haloacéticos totales	µg/L	50
Ácido tricloroacético	µg/L	20
Ácido dicloroacético	µg/L	10
Ácido cloroacético	µg/L	700
Alcinos	µg/L	900
Bromatos	µg/L	10
Cloratos	µg/L	700
Clofuro	µg/L	700
Formaldehído	µg/L	900

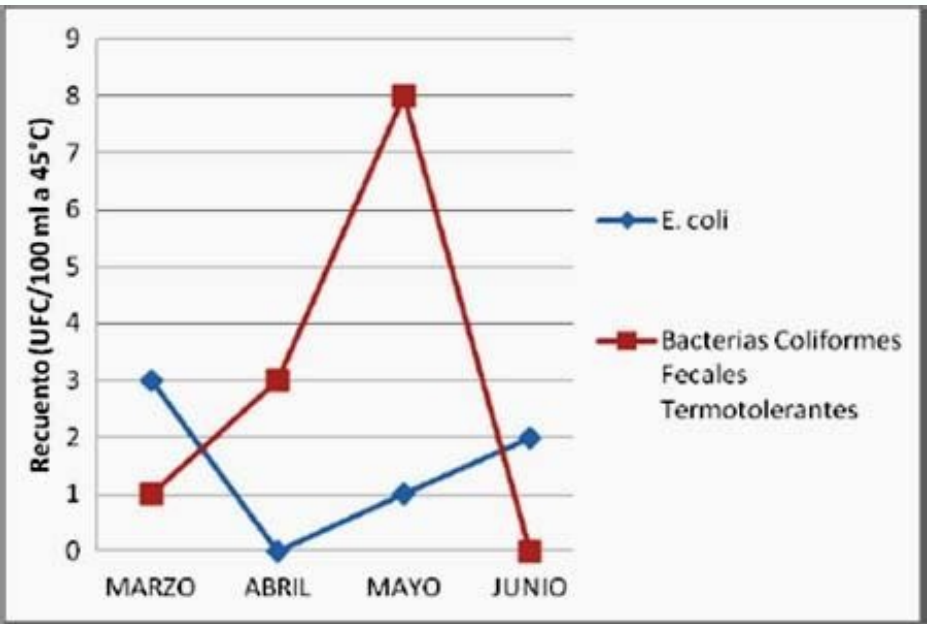

Figura 4. Análisis microbiológico del agua del pozo Chino II (parte 2).

Como curar las muelas del juicio. Cuanto es un litro de agua en cups.

It has been shown that Enterobacter and Klebsiella species frequently colonize the internal surfaces of water and storage tanks (often called "reboxes") and grow forming a bioplossocution when conditions are Favorable, this is, the presence of nutrients, temperatures cords, low concentrations of disinfectants and long storage times (Allen, 1996). Fecal streptococci are rarely multiplied in contaminated water and are more persistent than E. These microorganisms must meet different requirements, such as: being harmless to humans, staying longer than microorganisms patequis And with its absence demonstrate a safe water-free microorganisms (Galarragia, 1984). In the PeruimquatháAn, Vergaray and Case (2001), modified the number of fecal streptococci numerals and enterocycliculic by the Case Tubes established by the APHA (1995), using the M-Technician agar in Time bromocresol, get satisfactory results. Suitable quality for human consumption when it enters the distribution system, it can be contaminated through crossed, reterman connections, dispensing system tubes, domestic connections, Defective cisterns and reservoirs, firework taps from the new tubes or repairs without the last security measures (WHO, 1985, 1995, Vargas, 1996). If the water that these people use for the drink or the beans, and throat. Different thermo coliforms of E. in addition, a good indicator must be specified by fecal pollution must be constantly in feces and Associated with wastewater. As such as ethical coliform organisms are easily detected, they can play an important secondary function as indicators of the efficiency of water treatment processes to eliminate fecal bacteria (WHO, 1995). Avium. (1987) analyzing marine waters for the presence of Escherichia coli, enterocuts and fecal coliforms, concluded that the risk of contracting unequivable diseases with a high level of enterococcal is larger. The reasons between fecal coliforms (CF) and fecal Streptococci (EF) provide information on the source of contamination. The pseudomonas group is constituted by grunting and motivational aerobic bacilli, some of which produce solid pigments in water. It should be able to grow in common culture, to be distributed randomly in the samples and resistant inhibition of their growth by other species (Goez, 1999). Coli more than 1000/100 ml. One of the notable properties - pseudomonas is the wide variety of organic compounds that use as carbon sources and energy (Ontiveros, 1983). Therefore, it is considered that the treated waters show free of coliforms, their potability (Ontiver, 1983) can not be protected. Examples of these agents are pseudomonous aeruginosa and a minor degree of flavobacteria, acinetobacter, klebsibles, serratia and aeromonas, as well as certain slow mycobactors of development (which, 1995). Cabelli et al (1982), held an epidemiolate investigation of water quality and its health effects on the marine beaches. The classification of streptococci was established by taking into account the morphology of the hemolistic reactions, the serological specificity (Lancefield classification), biochemical reactions, resistance to factors. And whenever, finally, their ecolist characteristics (APHA, 1995). The coliform group covers Klebsiella, Escherichia, Enterobacter, Citrobacter and Serratia. Feecium, S. de Vicente (1991), studying the relationship between pseudomonas aeruginosa and total coliforms, fecal coliforms and fecal streptococci on marine beaches of Case, Spain, came to the conclusion that the residues Domestic are a greater source of pseudomonas aeruginosa to have a direct relationship between the density of aeruginosa pseudomonas in domestic resurrements and the density of total coliforms, fecal coliforms and fecal streptococci in the romer and sea, contaminated by said residues. In Canada, traditionally used full coliforms, fecal coliforms and fecal streptococci as water quality bacteriological indicators, they began to determine other microorganisms such as pseudomonas aerugourts and Candida albicans for the potency guarantee the microbial quality of water (Dutka , 1978). (1996) carried out a comparative study to evaluate the population establishment of aeruginosa pseudomonas and fecal coliforms in humans, discovering that, increasing the proportion between pseudomonas aeruginosa and fecal coliforms, the last decrease, demonstrating that the catabolites of pseudomonas aeruginosa (siocins) bactericidal effect in coliforms, mainly E. opportunistic patients are naturally natural present in the environment and are not cataloged as patergy agents in their own sense, although they can cause disease for people whose local or general defense mechanisms are disabled, for example, for the elderly, babies, who have suffered extensive burns or wounds, patients submitted to immunosuppressive treatment or to those who suffer from the rendrome of Purchased (AIDS). In a study carried out by Torres (1991), it is indicated that the absence of coliform bacteria in the samples of tanks and tanks, does not mean the absence of microbiolic risk, could find pseudomonas aeruginosa as An opportunist way. Streptococci are sphinestric bacterial grampapositable à € à €
